Quick Answers to Common Questions

### Start With Your Energy Bills

Let's face it - most folks calculate solar power needs because they're tired of unpredictable utility costs. In places like California or Germany, where electricity prices keep climbing, the first step is digging up your past 12 months of energy bills. Why? Well, your historical usage patterns reveal more than you'd think.

Take my neighbor in Texas - she initially guessed she needed a 10kW system. But when we crunched the numbers, her peak summer AC usage spiked to 1,400 kWh/month! That's nearly double her winter consumption. Moral of the story? Average monthly use can be misleading.

### Sunlight Hours Aren't What You Think

Here's where people slip up: confusing daylight hours with peak sun hours. Phoenix might get 6.5 daily peak hours, while London averages just 2.7. But wait, no - that doesn't mean London can't benefit from solar! You'd just need more panels or efficient micro-inverters to compensate.

A simple formula I've used for clients:

Daily energy need (kWh) ÷ Peak sun hours = System size (kW)

Add 20-25% buffer for inefficiencies

### When Geography Throws Curveballs

Australia's solar adopters learned this the hard way during the 2022 heatwaves. Panels lost 10-15% efficiency in 45°C temperatures - something installers rarely mention. If you're in Dubai or Mumbai, you'll need to derate system performance by at least 12% for thermal losses.

Consider this real-world twist: A Berlin household using 4,000 kWh/year would need a 4kW system. But shift that same family to Seattle? Suddenly it's a 6kW setup. That's why blanket "solar calculators" often miss the mark.

# How Do I Calculate Solar Power Needs

## The Battery Equation Changes Everything

Thinking about going off-grid? Determining solar requirements gets trickier. During Germany's 2023 energy crisis, households prioritizing battery storage doubled their system costs - but slashed grid dependence by 80%.

Here's a pro tip: Size your battery bank to cover 1-2 days of usage. For a home consuming 30kWh daily, that's 36-72kWh storage. But remember, lithium-ion batteries shouldn't discharge below 20% regularly. Do the math:  $72\text{kWh} \div 0.8 = 90\text{kWh}$  actual capacity needed.

## Burning Questions Answered

Q: How does snow affect my solar calculation?

A: Montreal residents add 15-20% system size to account for winter snow cover - panels might produce 40% less January output.

Q: Can I future-proof for an EV?

A: Absolutely. A Tesla Model 3 adds ~4,000 kWh/year. Tack that onto your existing needs when sizing a solar system.

Q: Do smart appliances change the game?

A: Big time. South Korea's AI-powered homes reduce energy waste by 18% - meaning smaller, cheaper solar setups.
